### 2. Bound-Preserving Methods Using First-Order DG Scheme

#### 2.1. Cartesian Coordinates

This section closely follows Qin et al. (2016).

#### 2.1.1. Set of Admissible States

We consider a one-dimensional system of conservation laws:

$$\partial_t \mathbf{U} + \partial_x \mathbf{F}(\mathbf{U}) = \mathbf{0},\tag{5}$$

where U is a vector of conserved variables, defined as:

$$U \longrightarrow \begin{pmatrix} D \\ S \\ \tau \end{pmatrix} = \begin{pmatrix} \rho W \\ \rho h W^2 v \\ \rho W (h W - 1) - p \end{pmatrix}, \tag{6}$$

and F(U) are the fluxes of those conserved quantities:

$$\boldsymbol{F}(\boldsymbol{U}) \longrightarrow \begin{pmatrix} \rho W \, v \\ \rho \, h \, W^2 \, v^2 + p \\ \rho \, h \, W^2 \, v - D \, v \end{pmatrix}. \tag{7}$$

The physics leads us to define a set of admissible states,  $\mathcal{G}_p$  (the subscript p stands for primitive), as:

$$\mathcal{G}_p \equiv \left\{ \mathbf{U} \middle| \rho > 0, \, p > 0, \, v^2 < 1 \right\}. \tag{8}$$

It is shown in Mignone & Bodo (2005) that  $\mathcal{G}$  is a convex set<sup>3</sup> and can equivalently be written in terms of the conserved variables as:

$$\mathcal{G} \equiv \left\{ U \middle| D > 0, \, \tau + D > \sqrt{D^2 + S^2} \right\}. \tag{9}$$

# 2.1.2. Time-Step Derivation/CFL Condition

For the first-order DG method using forward-Euler time-stepping, we evolve the vector of conserved variables as:

$$\overline{\boldsymbol{U}}_{i}^{n+1} = \overline{\boldsymbol{U}}_{i}^{n} - \eta_{i} \left[ \hat{\boldsymbol{F}} \left( \overline{\boldsymbol{U}}_{i}^{n}, \overline{\boldsymbol{U}}_{i+1}^{n} \right) - \hat{\boldsymbol{F}} \left( \overline{\boldsymbol{U}}_{i-1}^{n}, \overline{\boldsymbol{U}}_{i}^{n} \right) \right], \tag{10}$$

 $<sup>^3</sup>$ Convex in the sense that if  $U_1 \in \mathcal{G}$  and  $U_2 \in \mathcal{G}$ , then  $\alpha_1 U_1 + \alpha_2 U_2 \in \mathcal{G}$ , where  $\alpha_1, \alpha_2 \in [0,1]$  and  $\alpha_1 + \alpha_2 = 1$ .

where

$$\overline{U}_i \equiv \frac{1}{\Delta x_i} \int_{x_{i-\frac{1}{2}}}^{x_{i+\frac{1}{2}}} U_i dx, \tag{11}$$

 $\eta_i \equiv \Delta t_i/\Delta x_i$ , and  $\hat{F}$  is the numerical flux. In this document we use the local Lax-Friedrichs flux, defined as:

$$\hat{\boldsymbol{F}}(a,b) = \frac{1}{2} \left[ \boldsymbol{F}(a) + \boldsymbol{F}(b) - \alpha_{ab}(b-a) \right], \tag{12}$$

where a and b represent the state of the fluid in two different elements,  $\alpha_{ab}$  is an estimate for the wave-speed:

$$\alpha_{ab} = \max \left[ \alpha \left( a \right), \alpha \left( b \right) \right],\tag{13}$$

and  $\alpha$  is the largest (in absolute value) eigenvalue of the flux-Jacobian:

$$\alpha = \left| \left| \frac{\partial \mathbf{F}}{\partial \mathbf{U}} \right| \right|. \tag{14}$$

Using this we define the following variables:

$$\alpha_{i+\frac{1}{2}} = \max \left[ \alpha \left( \overline{\boldsymbol{U}}_i \right), \alpha \left( \overline{\boldsymbol{U}}_{i+1} \right) \right], \qquad \alpha_{i-\frac{1}{2}} = \max \left[ \alpha \left( \overline{\boldsymbol{U}}_{i-1} \right), \alpha \left( \overline{\boldsymbol{U}}_i \right) \right]. \tag{15}$$

Substituting (12) with (15) into (10):

$$\overline{\boldsymbol{U}}_{i}^{n+1} = \overline{\boldsymbol{U}}_{i}^{n} - \frac{\eta_{i}}{2} \left[ \boldsymbol{F} \left( \overline{\boldsymbol{U}}_{i}^{n} \right) + \boldsymbol{F} \left( \overline{\boldsymbol{U}}_{i+1}^{n} \right) - \alpha_{i+\frac{1}{2}} \left( \overline{\boldsymbol{U}}_{i+1}^{n} - \overline{\boldsymbol{U}}_{i}^{n} \right) \right. \\
\left. - \boldsymbol{F} \left( \overline{\boldsymbol{U}}_{i}^{n} \right) - \boldsymbol{F} \left( \overline{\boldsymbol{U}}_{i-1}^{n} \right) + \alpha_{i-\frac{1}{2}} \left( \overline{\boldsymbol{U}}_{i}^{n} - \overline{\boldsymbol{U}}_{i-1}^{n} \right) \right] \\
= \left[ 1 - \frac{\eta_{i}}{2} \left( \alpha_{i+\frac{1}{2}} + \alpha_{i-\frac{1}{2}} \right) \right] \overline{\boldsymbol{U}}_{i}^{n} + \frac{\eta_{i}}{2} \alpha_{i+\frac{1}{2}} \left[ \overline{\boldsymbol{U}}_{i+1}^{n} - \frac{1}{\alpha_{i+\frac{1}{2}}} \boldsymbol{F} \left( \overline{\boldsymbol{U}}_{i+1}^{n} \right) \right] \\
+ \frac{\eta_{i}}{2} \alpha_{i-\frac{1}{2}} \left[ \overline{\boldsymbol{U}}_{i-1}^{n} + \frac{1}{\alpha_{i-\frac{1}{2}}} \boldsymbol{F} \left( \overline{\boldsymbol{U}}_{i-1}^{n} \right) \right] \\
= \left[ 1 - \frac{\eta_{i}}{2} \left( \alpha_{i+\frac{1}{2}} + \alpha_{i-\frac{1}{2}} \right) \right] \overline{\boldsymbol{U}}_{i}^{n} + \frac{\eta_{i}}{2} \alpha_{i+\frac{1}{2}} \overline{\boldsymbol{H}}^{-} \left( \overline{\boldsymbol{U}}_{i+1}^{n}, \alpha_{i+\frac{1}{2}} \right) + \frac{\eta_{i}}{2} \alpha_{i+\frac{1}{2}} \overline{\boldsymbol{H}}^{+} \left( \overline{\boldsymbol{U}}_{i-1}^{n}, \alpha_{i-\frac{1}{2}} \right), \quad (16)$$

where

$$\overline{\boldsymbol{H}}^{\pm}\left(\overline{\boldsymbol{U}},\alpha\right) \equiv \overline{\boldsymbol{U}} \pm \frac{1}{\alpha} \boldsymbol{F}\left(\overline{\boldsymbol{U}}\right). \tag{17}$$

The proof that  $\overline{H}^{\pm} \in \mathcal{G}$  is given in Qin et al. (2016). Therefore, we see that with a restriction on  $\alpha_{i\pm\frac{1}{2}}$  that (16) is a convex combination. The restriction is (recalling that  $\eta_i = \Delta t_i/\Delta x_i$ ):

$$1 - \frac{\eta_{i}}{2} \left( \alpha_{i + \frac{1}{2}} + \alpha_{i - \frac{1}{2}} \right) > 0 \implies \frac{\eta_{i}}{2} \left( \alpha_{i + \frac{1}{2}} + \alpha_{i - \frac{1}{2}} \right) < 1 \implies \Delta t_{i} < \frac{2 \Delta x_{i}}{\alpha_{i + \frac{1}{2}} + \alpha_{i - \frac{1}{2}}} \leq \frac{\Delta x_{i}}{\max \left( \alpha_{i \pm \frac{1}{2}} \right)}. \quad (18)$$

We want a time-step that is the same for all elements at a given time, so we tighten the restriction to:

$$\Delta t < \min_{i} \left( \frac{\Delta x_{i}}{\max\left(\alpha_{i \pm \frac{1}{2}}\right)} \right) = \frac{\Delta x}{\max_{i} \left(\alpha_{i \pm \frac{1}{2}}\right)},\tag{19}$$

where the equality follows for a uniform mesh, i.e.  $\Delta x_i = \Delta x \, \forall i$ .

#### 2.2. Curvilinear Coordinates

NOTE: We assume a conformally-flat, time-independent spatial three-metric:

$$\gamma_{ij}\left(x^{k},t\right) \longrightarrow \psi^{4}\left(x^{k}\right) \overline{\gamma_{ii}}\left(x^{k}\right),$$
(20)

where  $\psi\left(x^{k}\right)$  is the conformal factor and  $\overline{\gamma}_{ii}$  is the flat-space metric.

#### 2.2.1. Set of Admissible States

We again consider a one-dimensional system of conservation laws, but this time with a curvilinear metric:

$$\partial_t(\sqrt{\gamma}\,\boldsymbol{U}) + \partial_1(\sqrt{\gamma}\,\boldsymbol{F}) = \sqrt{\gamma}\,\boldsymbol{Q},\tag{21}$$

where U is given by:

$$U \longrightarrow \begin{pmatrix} D \\ S_1 \\ \tau \end{pmatrix} = \begin{pmatrix} \rho W \\ \rho h W^2 v_1 \\ \rho W (h W - 1) - p \end{pmatrix} = \begin{pmatrix} \rho W \\ \rho h W^2 \gamma_{1j} v^j \\ \rho W (h W - 1) - p \end{pmatrix}, \tag{22}$$

F(U) are the fluxes of those conserved quantities:

$$F(U) \longrightarrow \begin{pmatrix} D v^{1} \\ S^{1} v_{1} + p \delta^{1}_{1} \\ S^{1} - D v^{1} \end{pmatrix} = \begin{pmatrix} \rho W v^{1} \\ \rho h W^{2} v^{1} v_{1} + p \\ \rho h W^{2} v^{1} - D v^{1} \end{pmatrix} = \begin{pmatrix} \rho W v^{1} \\ \rho h W^{2} \gamma_{1j} v^{1} v^{j} + p \\ \rho h W^{2} v^{1} - D v^{1} \end{pmatrix}, \tag{23}$$

and Q is a source term:

$$Q \longrightarrow \begin{pmatrix} 0 \\ \frac{1}{2} P^{kj} \partial_1 \gamma_{kj} \\ 0 \end{pmatrix} = \begin{pmatrix} \frac{1}{2} \left[ P^{11} \partial_1 \gamma_{11} + P^{22} \partial_1 \gamma_{22} + P^{33} \partial_1 \gamma_{33} \right] \end{pmatrix}$$
(24)

$$= \left(P^{11} h_1 \partial_1 h_1 + P^{22} h_2 \partial_1 h_2 + P^{33} h_3 \partial_1 h_3\right), \tag{25}$$

where we have used the fact that  $\gamma_{jj} = (h_j)^2$ . The  $P^{kj}$  are components of the pressure tensor:

$$P^{kj} = S^k v^j + p \gamma^{kj} = \gamma^{k\ell} S_\ell v^j + p \gamma^{kj} = \gamma^{k\ell} S_\ell v^j + p \gamma^{k\ell} \delta^j_{\ell} = \gamma^{k\ell} \left( S_\ell v^j + p \delta^j_{\ell} \right).$$
 (26)

Since the spatial three-metric is diagonal we must have that  $\ell=k$ . We can therefore simplify further:

$$P^{kj} = \gamma^{kk} \left( S_k v^j + p \, \delta_k^j \right) = \frac{1}{\gamma_{kk}} \left( S_k v^j + p \, \delta_k^j \right) = \frac{1}{\left( h_k \right)^2} \left( S_k v^j + p \, \delta_k^j \right) \tag{27}$$

For the pressure-tensor sum, we then have:

$$P^{kj} \partial_1 \gamma_{kj} = P^{kk} \partial_1 \gamma_{kk} = P^{kk} \partial_1 (h_k)^2 = 2 P^{kk} h_k \partial_1 h_k = \frac{2}{h_k} (S_k v^k + p) \partial_1 h_k.$$
 (28)

These definitions lead us to define the same set of admissible states as before, namely:

$$\mathcal{G}_p \equiv \left\{ \mathbf{U} \middle| \rho > 0, \, p > 0, \, v^2 < 1 \right\},\tag{29}$$

the only difference being that  $v^2$  now involves the metric:

$$v^2 = v^j v_j = \gamma_{kj} v^k v^j. (30)$$

Before continuing, we show that the introduction of the metric doesn't affect the translation between  $\mathcal{G}_p$  and  $\mathcal{G}$ ...(SD: I've shown this, just need to TeX it up)

### 2.2.2. Time-Step Derivation/CFL Condition

We start by integrating both sides over  $dx^1$  and dividing by the volume,  $\Delta V_i$ :

$$\frac{1}{\Delta V_{i}} \int_{x_{i-\frac{1}{2}}^{1}}^{x_{i+\frac{1}{2}}^{1}} \partial_{t}(\sqrt{\gamma} \mathbf{U}_{i}) dx^{1} + \frac{1}{\Delta V_{i}} \int_{x_{i-\frac{1}{2}}^{1}}^{x_{i+\frac{1}{2}}^{1}} \partial_{1}(\sqrt{\gamma} \mathbf{F}(\mathbf{U}_{i})) dx^{1} = \frac{1}{\Delta V_{i}} \int_{x_{i-\frac{1}{2}}^{1}}^{x_{i+\frac{1}{2}}^{1}} \sqrt{\gamma} \mathbf{Q}_{i} dx^{1},$$
(31)

where:

$$\Delta V_i = \int_{x_{i-\frac{1}{2}}}^{x_{i+\frac{1}{2}}^1} dV = \int_{x_{i-\frac{1}{2}}}^{x_{i+\frac{1}{2}}^1} \sqrt{\gamma} \, dx^1.$$
 (32)

By defining the cell-average as:

$$\overline{\boldsymbol{W}}_{i} \equiv \frac{1}{\Delta V_{i}} \int_{x_{i-\frac{1}{2}}}^{x_{i+\frac{1}{2}}^{1}} \boldsymbol{W}_{i} \, dV, \tag{33}$$

we have:

$$\frac{d\overline{\boldsymbol{U}}_{i}}{dt} + \frac{1}{\Delta V_{i}} \left( \sqrt{\gamma} \,\hat{\boldsymbol{F}} \left( \overline{\boldsymbol{U}} \right) \right) \Big|_{x_{i-\frac{1}{2}}}^{x_{i+\frac{1}{2}}} = \overline{\boldsymbol{Q}}_{i}, \tag{34}$$

or, using the common notation of the time step being represented as a superscript and the spatial element represented by a subscript:

$$\overline{\boldsymbol{U}}_{i}^{n+1} = \overline{\boldsymbol{U}}_{i}^{n} - \frac{\Delta t_{i}}{\Delta V_{i}} \left[ \sqrt{\gamma_{i+\frac{1}{2}}} \, \hat{\boldsymbol{F}}_{i+\frac{1}{2}}^{n} - \sqrt{\gamma_{i-\frac{1}{2}}} \, \hat{\boldsymbol{F}}_{i-\frac{1}{2}}^{n} \right] + \Delta t_{i} \, \overline{\boldsymbol{Q}}_{i}^{n}. \tag{35}$$

Now we define a parameter a la Zhang & Shu (2011):  $\varepsilon \in (0,1)$ , such that (NOTE: Zhang & Shu (2011) set  $\varepsilon = 1/2$ ):

$$\overline{\boldsymbol{U}}_{i}^{n} = \varepsilon \, \overline{\boldsymbol{U}}_{i}^{n} + (1 - \varepsilon) \, \overline{\boldsymbol{U}}_{i}^{n}. \tag{36}$$

We can use the first term to balance out the term in the square brackets and the second term to balance out the source term.

So, we get:

$$\overline{\boldsymbol{U}}_{i}^{n+1} = \varepsilon \left\{ \overline{\boldsymbol{U}}_{i}^{n} - \frac{\Delta t_{i}}{\varepsilon \Delta V_{i}} \left[ \sqrt{\gamma_{i+\frac{1}{2}}} \, \hat{\boldsymbol{F}}_{i+\frac{1}{2}}^{n} - \sqrt{\gamma_{i-\frac{1}{2}}} \, \hat{\boldsymbol{F}}_{i-\frac{1}{2}}^{n} \right] \right\} + (1 - \varepsilon) \, \overline{\boldsymbol{U}}_{i}^{n} + \Delta t_{i} \, \overline{\boldsymbol{Q}}_{i}^{n}$$
(37)

$$= \varepsilon \left\{ \overline{\boldsymbol{U}}_{i}^{n} - \eta_{i} \left[ \sqrt{\gamma_{i+\frac{1}{2}}} \hat{\boldsymbol{F}} \left( \overline{\boldsymbol{U}}_{i+1}^{n}, \overline{\boldsymbol{U}}_{i}^{n} \right) - \sqrt{\gamma_{i-\frac{1}{2}}} \hat{\boldsymbol{F}} \left( \overline{\boldsymbol{U}}_{i}^{n}, \overline{\boldsymbol{U}}_{i-1}^{n} \right) \right] \right\} + (1 - \varepsilon) \overline{\boldsymbol{U}}_{i}^{n} + \Delta t_{i} \overline{\boldsymbol{Q}}_{i}^{n}$$
(38)

$$= \varepsilon \, \overline{H}_1 + (1 - \varepsilon) \, \overline{H}_2, \tag{39}$$

where

$$\overline{\boldsymbol{H}}_{1} \equiv \overline{\boldsymbol{U}}_{i}^{n} - \eta_{i} \left[ \sqrt{\gamma}_{i+\frac{1}{2}} \, \hat{\boldsymbol{F}} \left( \overline{\boldsymbol{U}}_{i+1}^{n}, \overline{\boldsymbol{U}}_{i}^{n} \right) - \sqrt{\gamma}_{i-\frac{1}{2}} \, \hat{\boldsymbol{F}} \left( \overline{\boldsymbol{U}}_{i}^{n}, \overline{\boldsymbol{U}}_{i-1}^{n} \right) \right], \tag{40}$$

$$\overline{\boldsymbol{H}}_2 \equiv \overline{\boldsymbol{U}}_i^n + \frac{\Delta t_i}{1 - \varepsilon} \, \overline{\boldsymbol{Q}}_i^n,\tag{41}$$

and

$$\eta_i \equiv \frac{\Delta t_i}{\varepsilon \, \Delta V_i}.\tag{42}$$

We proceed by focusing on each term individually, starting with the numerical flux term,  $\overline{H}_1$ .

#### 2.2.3. Numerical flux term

We have to show that  $\overline{H}_1 \in \mathcal{G}$ . We again we use the Local-Lax-Friedrichs flux, (12), yielding for  $\overline{H}_1$ :

$$\overline{\boldsymbol{U}}_{i}^{n} - \frac{\eta_{i}}{2} \left\{ \sqrt{\gamma}_{i+\frac{1}{2}} \left[ \boldsymbol{F} \left( \overline{\boldsymbol{U}}_{i+1}^{n} \right) + \boldsymbol{F} \left( \overline{\boldsymbol{U}}_{i}^{n} \right) - \alpha_{i+\frac{1}{2}} \left( \overline{\boldsymbol{U}}_{i+1}^{n} - \overline{\boldsymbol{U}}_{i}^{n} \right) \right]$$

$$\tag{43}$$

$$-\sqrt{\gamma}_{i-\frac{1}{2}}\left[\boldsymbol{F}\left(\overline{\boldsymbol{U}}_{i}^{n}\right)+\boldsymbol{F}\left(\overline{\boldsymbol{U}}_{i-1}^{n}\right)-\alpha_{i-\frac{1}{2}}\left(\overline{\boldsymbol{U}}_{i}^{n}-\overline{\boldsymbol{U}}_{i-1}^{n}\right)\right]\right\} \tag{44}$$

$$= \left(1 - \frac{1}{2} \eta_i \sqrt{\gamma_{i+\frac{1}{2}}} \alpha_{i+\frac{1}{2}} - \frac{1}{2} \eta_i \sqrt{\gamma_{i-\frac{1}{2}}} \alpha_{i-\frac{1}{2}}\right) \overline{U}_i^n \tag{45}$$

$$-\frac{1}{2}\eta_{i}\sqrt{\gamma_{i+\frac{1}{2}}}\boldsymbol{F}\left(\overline{\boldsymbol{U}}_{i}^{n}\right) + \frac{1}{2}\eta_{i}\sqrt{\gamma_{i-\frac{1}{2}}}\boldsymbol{F}\left(\overline{\boldsymbol{U}}_{i}^{n}\right) \tag{46}$$

$$+\frac{1}{2}\eta_{i}\sqrt{\gamma_{i-\frac{1}{2}}}\alpha_{i-\frac{1}{2}}\left[\overline{\boldsymbol{U}}_{i-1}^{n}+\frac{1}{\alpha_{i-\frac{1}{2}}}\boldsymbol{F}\left(\overline{\boldsymbol{U}}_{i-1}^{n}\right)\right]+\frac{1}{2}\eta_{i}\sqrt{\gamma_{i+\frac{1}{2}}}\alpha_{i+\frac{1}{2}}\left[\overline{\boldsymbol{U}}_{i+1}^{n}-\frac{1}{\alpha_{i+\frac{1}{2}}}\boldsymbol{F}\left(\overline{\boldsymbol{U}}_{i+1}^{n}\right)\right].$$
(47)

Now we add and subtract  $\frac{1}{2} \eta_i \sqrt{\gamma_{i+\frac{1}{2}}} \alpha_{i+\frac{1}{2}} \overline{U}_i^n$  and  $\frac{1}{2} \eta_i \sqrt{\gamma_{i-\frac{1}{2}}} \alpha_{i-\frac{1}{2}} \overline{U}_i^n$ , yielding

$$\left(1 - \eta_i \sqrt{\gamma_{i+\frac{1}{2}}} \alpha_{i+\frac{1}{2}} - \eta_i \sqrt{\gamma_{i-\frac{1}{2}}} \alpha_{i-\frac{1}{2}}\right) \overline{U}_i^n \tag{48}$$

$$+\frac{1}{2}\eta_{i}\sqrt{\gamma_{i+\frac{1}{2}}}\alpha_{i+\frac{1}{2}}\left[\overline{\boldsymbol{U}}_{i}^{n}-\frac{1}{\alpha_{i+\frac{1}{2}}}\boldsymbol{F}\left(\overline{\boldsymbol{U}}_{i}^{n}\right)\right]+\frac{1}{2}\eta_{i}\sqrt{\gamma_{i-\frac{1}{2}}}\alpha_{i-\frac{1}{2}}\left[\overline{\boldsymbol{U}}_{i}^{n}+\frac{1}{\alpha_{i-\frac{1}{2}}}\boldsymbol{F}\left(\overline{\boldsymbol{U}}_{i}^{n}\right)\right]$$

$$(49)$$

$$+\frac{1}{2}\eta_{i}\sqrt{\gamma_{i-\frac{1}{2}}}\alpha_{i-\frac{1}{2}}\left[\overline{\boldsymbol{U}}_{i-1}^{n}+\frac{1}{\alpha_{i-\frac{1}{2}}}\boldsymbol{F}\left(\overline{\boldsymbol{U}}_{i-1}^{n}\right)\right]+\frac{1}{2}\eta_{i}\sqrt{\gamma_{i+\frac{1}{2}}}\alpha_{i+\frac{1}{2}}\left[\overline{\boldsymbol{U}}_{i+1}^{n}-\frac{1}{\alpha_{i+\frac{1}{2}}}\boldsymbol{F}\left(\overline{\boldsymbol{U}}_{i+1}^{n}\right)\right].$$
 (50)

All of the terms in square brackets are similar to the  $\overline{H}$  quantities in Qin et al. (2016), and are therefore in  $\mathcal{G}$ . It can easily be seen that the sum of the coefficients is unity. The final condition is that the coefficient of  $\overline{U}_i^n > 0$ , or (recalling that  $\eta_i = \Delta t_i / (\varepsilon \Delta V_i)$ ):

$$1 - \eta_{i} \sqrt{\gamma_{i+\frac{1}{2}}} \alpha_{i+\frac{1}{2}} - \eta_{i} \sqrt{\gamma_{i-\frac{1}{2}}} \alpha_{i-\frac{1}{2}} > 0 \implies \eta_{i} \left( \sqrt{\gamma_{i+\frac{1}{2}}} \alpha_{i+\frac{1}{2}} + \sqrt{\gamma_{i-\frac{1}{2}}} \alpha_{i-\frac{1}{2}} \right) < 1$$
 (51)

$$\implies \Delta t_i < \frac{\varepsilon \, \Delta V_i}{\sqrt{\gamma_{i+\frac{1}{2}}} \, \alpha_{i+\frac{1}{2}} + \sqrt{\gamma_{i-\frac{1}{2}}} \, \alpha_{i-\frac{1}{2}}} \le \frac{\varepsilon \, \Delta V_i}{2 \, \max\left(\sqrt{\gamma_{i+\frac{1}{2}}} \, \alpha_{i+\frac{1}{2}}\right)}. \tag{52}$$

Again we want a time-step that is the same for all elements at a given time, so:

$$\Delta t < \min_{i} \left( \frac{\varepsilon \, \Delta V_{i}}{2 \max \left( \sqrt{\gamma}_{i \pm \frac{1}{2}} \, \alpha_{i \pm \frac{1}{2}} \right)} \right). \tag{53}$$

We close the numerical flux section by writing the explicit form of the time-step for spherical-polar coordinates.

## Time-step for Spherical-Polar Coordinates

For spherical-polar coordinates in 1-D we have that  $\Delta V_i=1/3\left(r_{i+\frac{1}{2}}^3-r_{i-\frac{1}{2}}^3\right)$ , and (assuming  $\alpha_{i\pm\frac{1}{2}}=1\ \forall\ i$ )  $\max\left(\sqrt{\gamma}_{i\pm\frac{1}{2}}\ \alpha_{i\pm\frac{1}{2}}\right)=r_{i+\frac{1}{2}}^2$ , so:

$$\Delta t < \min_{i} \left\{ \frac{\varepsilon 1/3 \left[ r_{i+\frac{1}{2}}^{3} - r_{i-\frac{1}{2}}^{3} \right]}{2 r_{i+\frac{1}{2}}^{2}} \right\}$$
 (54)

$$= \min_{i} \left\{ \frac{\varepsilon}{6} \, r_{i+\frac{1}{2}} \left[ 1 - \frac{r_{i-\frac{1}{2}}^{3}}{r_{i+\frac{1}{3}}^{3}} \right] \right\} \tag{55}$$

$$= \min_{i} \left\{ \frac{\varepsilon}{6} \, r_{i + \frac{1}{2}} \left[ 1 - \left( 1 - \frac{\Delta r_{i}}{r_{i + \frac{1}{2}}} \right)^{3} \right] \right\} \tag{56}$$

$$= \min_{i} \left\{ \frac{\varepsilon}{6} \, r_{i + \frac{1}{2}} \left[ 1 - \left( 1 + \left( \frac{\Delta r_i}{r_{i + \frac{1}{2}}} \right)^2 - 2 \frac{\Delta r_i}{r_{i + \frac{1}{2}}} \right) \left( 1 - \frac{\Delta r_i}{r_{i + \frac{1}{2}}} \right) \right] \right\} \tag{57}$$

$$= \min_{i} \left\{ \frac{\varepsilon}{6} \, r_{i + \frac{1}{2}} \left[ \left( \frac{\Delta r_{i}}{r_{i + \frac{1}{2}}} \right)^{3} - 3 \left( \frac{\Delta r_{i}}{r_{i + \frac{1}{2}}} \right)^{2} + 3 \frac{\Delta r_{i}}{r_{i + \frac{1}{2}}} \right] \right\}$$
 (58)

$$= \min_{i} \left\{ \frac{\varepsilon}{6} \Delta r_{i} \left[ \left( \frac{\Delta r_{i}}{r_{i+\frac{1}{2}}} \right)^{2} - 3 \left( \frac{\Delta r_{i}}{r_{i+\frac{1}{2}}} \right) + 3 \right] \right\}. \tag{59}$$

We know that  $\Delta r_i/r_{i+\frac{1}{2}} \in [0,1]$ ; the minimum value of the quadratic function in this domain is unity. So, we have that for spherical-polar coordinates:

$$\Delta t < \frac{\varepsilon}{6} \min\left(\Delta r_i\right). \tag{60}$$

Next we handle the source term.

#### 2.2.4. Source term

For this section we drop the subscript i and the superscript n. We have to show that  $\overline{H}_2 \in \mathcal{G}$ , where

$$\overline{\boldsymbol{H}}_{2} = \begin{pmatrix} \overline{D} \\ \overline{S}_{1} + \frac{\Delta t}{2(1-\varepsilon)} \overline{P^{kk} \partial_{1} \gamma_{kk}} \\ \overline{\tau} \end{pmatrix}, \quad \left(\overline{H}_{2}\right)_{1} > 0, \quad \left(\overline{H}_{2}\right)_{3} + \left(\overline{H}_{2}\right)_{1} > \sqrt{\left(\overline{H}_{2}\right)_{1} \left(\overline{H}_{2}\right)_{1} + \left(\overline{H}_{2}\right)_{2} \left(\overline{H}_{2}\right)^{2}}. \quad (61)$$

It is clear that the first requirement for  $\overline{H}_2$  is met, i.e.  $\overline{D} > 0$ . The second requirement is:

$$\overline{D} + \overline{\tau} > \sqrt{\overline{D}^2 + \left[\overline{S}_1 + \frac{\Delta t}{2(1-\varepsilon)} \overline{P^{kk} \partial_1 \gamma_{kk}}\right] \left[\overline{S}^1 + \frac{\Delta t}{2(1-\varepsilon)} \overline{P^{kk} \partial_1 \gamma_{kk}}\right]}$$
(62)

$$= \sqrt{\overline{D}^2 + \left[\overline{S}_1 + \frac{\Delta t}{2(1-\varepsilon)}\overline{P^{kk}\partial_1\gamma_{kk}}\right]\left[\overline{S}^1 + \gamma^{11}\frac{\Delta t}{2(1-\varepsilon)}\overline{P^{kk}\partial_1\gamma_{kk}}\right]}$$
(63)

$$= \sqrt{\overline{D}^2 + \overline{S}_1 \, \overline{S}^1 + \gamma^{11} \left[ \frac{\overline{P^{kk} \, \partial_1 \gamma_{kk}}}{2 \, (1 - \varepsilon)} \right]^2 (\Delta t)^2 + \frac{\overline{P^{kk} \, \partial_1 \gamma_{kk}}}{2 \, (1 - \varepsilon)} \left[ \overline{S}_1 \, \gamma^{11} + \overline{S}^1 \right] \Delta t}$$
 (64)

$$=\sqrt{a\left(\Delta t\right)^{2}+b\,\Delta t+c}\geq0,\tag{65}$$

where

$$a = \left[ \frac{\overline{P^{kk} \, \partial_1 \gamma_{kk}}}{2\sqrt{\overline{\gamma_{11}}} \, (1 - \varepsilon)} \right]^2 \ge 0 \tag{66}$$

$$b = \frac{\overline{P^{kk}} \, \partial_1 \gamma_{kk}}{\overline{\gamma_{11}} \, (1 - \varepsilon)} \overline{S}_1 = \frac{2 \, \overline{S}_1}{\sqrt{\overline{\gamma_{11}}}} \sqrt{a} \tag{67}$$

$$c = \overline{D}^2 + \overline{S}_1 \, \overline{S}^1 \ge 0. \tag{68}$$

The condition for a quadratic function to be positive-definite is that a>0 (concave-up) and  $b^2-4ac<0$  (no real roots). The first condition is clearly met. For the second condition:

$$b^{2} - 4ac = \frac{4(\overline{S}_{1})^{2}}{\overline{\gamma}_{11}}a - 4a(\overline{D}^{2} + \overline{S}_{1}\overline{S}^{1}) = 4\overline{S}_{1}\overline{S}^{1}a - 4a\overline{D}^{2} - 4a\overline{S}_{1}\overline{S}^{1} = -4a\overline{D}^{2} < 0.$$
 (69)

So, the square root is always positive.

With that we have:

$$\overline{D}^{2} + \overline{\tau}^{2} + 2\overline{D}\overline{\tau} > a(\Delta t)^{2} + b\Delta t + c$$
(70)

$$\implies a\left(\Delta t\right)^2 + b\,\Delta t + c' < 0,\tag{71}$$

where:

$$c' = c - \overline{D}^2 - \overline{\tau}^2 - 2\overline{D}\overline{\tau} = \overline{S}_1\overline{S}^1 - \overline{\tau}^2 - 2\overline{D}\overline{\tau}.$$

$$(72)$$

This time we want to make sure that our function has at least one real root. We still have that a > 0, so now we check if  $b^2 - 4 a c' > 0$ :

$$b^{2} - 4ac' = \frac{4(\overline{S}_{1})^{2}}{\overline{\gamma_{11}}}a - 4a(\overline{S}_{1}\overline{S}^{1} - \overline{\tau}^{2} - 2\overline{D}\overline{\tau}) = 4a\overline{\tau}(\overline{\tau} + 2\overline{D}).$$
 (73)

Since  $\overline{\tau} \geq 0$ , we must have that  $\overline{\tau} > -2\overline{D}$ . But, from condition two for  $\overline{H}_2$  we have that  $\overline{\tau} > -\overline{D}$ , so this condition is automatically satisfied.

The solutions to this quadratic equation are:

$$\Delta t = \frac{-b}{2a} \pm \frac{1}{2a} \sqrt{b^2 - 4ac'} = \frac{-\overline{S}_1}{\sqrt{\overline{\gamma}_{11}} \sqrt{a}} \pm \frac{1}{2a} \sqrt{\frac{4\overline{S}_1^2}{\overline{\gamma}_{11}}} a - 4ac'}$$
 (74)

$$=\frac{-\overline{S}_1}{\sqrt{\overline{\gamma}_{11}}\sqrt{a}}\pm\frac{1}{\sqrt{\overline{\gamma}_{11}}\sqrt{a}}\sqrt{\overline{S}_1^2-c'\overline{\gamma}_{11}}=\frac{1}{\sqrt{\overline{\gamma}_{11}}\sqrt{a}}\left[-\overline{S}_1\pm\sqrt{\overline{S}_1^2-c'\overline{\gamma}_{11}}\right]$$
(75)

$$=\frac{1}{\sqrt{\overline{\gamma_{11}}}\sqrt{a}}\left[-\overline{S}_1 \pm \sqrt{\overline{\gamma_{11}}\left(\overline{\tau}^2 + 2\overline{D}\,\overline{\tau}\right)}\right] \tag{76}$$

$$= \frac{2(1-\varepsilon)}{\overline{P^{kk}} \, \partial_1 \, \gamma_{kk}} \left[ -\overline{S}_1 \pm \sqrt{\overline{\gamma_{11}} \left( \overline{\tau}^2 + 2 \, \overline{D} \, \overline{\tau} \right)} \right] \tag{77}$$

$$= \frac{2(1-\varepsilon)}{P^{kk}\,\partial_1\,\gamma_{kk}} \left[ -\overline{S}_1 \pm \sqrt{\overline{\gamma_{11}}\,\overline{\tau}\,(\overline{\tau}+2\,\overline{D})} \right]. \tag{78}$$

So, we end up with:

$$\Delta t < \min \left\{ \min_{i} \left( \frac{\varepsilon \, \Delta V_{i}}{2 \max \left( \sqrt{\gamma}_{i \pm \frac{1}{2}} \, \alpha_{i \pm \frac{1}{2}} \right)} \right), \min_{i}^{n} \left( \frac{2 \left( 1 - \varepsilon \right)}{P^{kk} \, \partial_{1} \, \gamma_{kk}} \left[ -\overline{S}_{1} \pm \sqrt{\overline{\gamma_{11}} \, \overline{\tau} \left( \overline{\tau} + 2 \, \overline{D} \right)} \right] \right) \right\}. \tag{79}$$

#### **2.3.** Demanding that q > 0

Sometimes it happens that the cell-average of q,  $q_K \equiv q(U_K) < 0$ , so our positivity limiter will fail. To get around this we modify the conserved energy,  $\tau$ , to demand that  $q = \varepsilon$ , where  $0 < \varepsilon \ll 1$ . The transformation we make is:

$$\tau_K \longrightarrow \alpha \, \tau_K, \quad \alpha > 1.$$
(80)

This modifies the definition of  $q_K$  from:

$$q_K = \tau_K + D_K - \sqrt{D_K^2 + S_K^2 + \varepsilon} < 0,$$
 (81)

to:

$$\varepsilon = \alpha \tau_K + D_K - \sqrt{D_K^2 + S_K^2 + \varepsilon}.$$
 (82)

Solving this for  $\alpha$ , we get:

$$\alpha = \tau_K^{-1} \left[ \varepsilon - D_K + \sqrt{D_K^2 + S_K^2 + \varepsilon} \right]. \tag{83}$$

## 3. Computing the Time-Step Using Higher-Order DG Schemes

When making the jump to higher-order DG schemes, we can simply do the same as in the first-order scheme, except we compute the quantities in all of the nodal points instead of using a cell-average. This is valid because the cell-average is a convex combination...(SD: Need to expand on this). The proof starts with the discretized equation valid at each quadrature point, q:

$$\boldsymbol{U}_{q}^{n+1} = \boldsymbol{U}_{q}^{n} + \Delta t \, \mathcal{L}_{q}^{n}, \tag{84}$$

where  $\mathcal{L}_q^n$  is a general form of the RHS at time  $t^n$ . If we define a vector  $\overline{\boldsymbol{U}} \equiv (\boldsymbol{U}_1, \cdots, \boldsymbol{U}_q, \cdots, \boldsymbol{U}_Q)^T$ , where Q is the total number of quadrature points, and  $\overline{\boldsymbol{W}} \equiv (\boldsymbol{W}_1, \cdots, \boldsymbol{W}_q, \cdots, \boldsymbol{W}_Q)^T$  as a vector of quadrature weights, then we can write the cell-average of  $\boldsymbol{U}$  as:

$$U_K \equiv \overline{\boldsymbol{W}}^T \overline{\boldsymbol{U}}.\tag{85}$$

If we then compute the cell-average of the above equation, we get:

$$\boldsymbol{U}_{K}^{n+1} = \boldsymbol{U}_{K}^{n} + \Delta t \, \overline{\boldsymbol{W}}^{T} \, \overline{\mathcal{L}}_{q}^{n} = \overline{\boldsymbol{W}}^{T} \left( \overline{\boldsymbol{U}}^{n} + \Delta t \, \overline{\mathcal{L}}^{n} \right)$$
(86)

#### 4. Recovery of Primitive Variables

In order to recover the primitive from the conserved variables we need to solve the nonlinear equation:

$$f(p) = p - \overline{p}(p) = 0, \tag{87}$$

where  $\bar{p}(p)$  is the pressure as obtained via the ideal gas equation of state with an initial guess, p:

$$\overline{p} = (\Gamma - 1) \rho \epsilon, \tag{88}$$

where

$$\rho = \rho(\mathbf{U}, p), \quad \epsilon = \epsilon(\mathbf{U}, p).$$
(89)

In order to solve this equation we make use of the bisection method, and therefore need bounds on our initial guess for the pressure.

#### 4.1. Upper and Lower Bounds for Pressure

We obtain a lower bound for the pressure with:

$$\tau = D(hW - 1) - p \implies p = -(\tau + D) + DhW \ge -(\tau + D) + DhW\sqrt{v^{i}v_{i}} = -(\tau + D) + \sqrt{S^{i}S_{i}}.$$
(90)

So, since the pressure must be non-negative, we have:

$$p \ge \text{MAX}\left[-\left(\tau + D\right) + \sqrt{S^i S_i}, \text{SqrtTiny}\right].$$
 (91)

For an upper bound, we first note that:

$$h = 1 + \frac{e+p}{\rho} = 1 + \frac{\Gamma}{\Gamma - 1} \frac{p}{\rho} = 1 + \frac{\Gamma}{\Gamma - 1} \frac{pW}{D}, \tag{92}$$

so,

$$\tau = D\left(W + \frac{\Gamma}{\Gamma - 1} \frac{pW^2}{D} - 1\right) - p = D\left(W - 1\right) + p\left(\frac{\Gamma}{\Gamma - 1}W^2 - 1\right) > p\left(\frac{\Gamma}{\Gamma - 1} - 1\right) = \frac{p}{\Gamma - 1}. \tag{93}$$

So,

$$p < (\Gamma - 1)\tau. \tag{94}$$

Typically,  $\Gamma - 1 < 3$ . So, we end up with:

$$p < 3\tau. \tag{95}$$
